FastSpeech 2: Implementation and Evaluation for English and Telugu

Comparative Acoustic Modeling across Svarah (English) and IndicTTS (Telugu)

Mohammed Saad-uddin

Email: reach.saad@outlook.com | Technical Report

Abstract: *This report presents the design, implementation, and empirical evaluation of a FastSpeech 2 neural text-to-speech (TTS) system trained independently on English (Svarah corpus) and Telugu (IndicTTS corpus). We discuss the feed-forward transformer architecture, variance adaptor components (duration, fundamental frequency F0, and energy predictors), and universal HiFi-GAN vocoder integration. Key modifications from the reference baseline include dynamic device handling, modern Librosa compatibility, and a native Telugu Akshara grapheme-to-phoneme front-end with conjunct consonant resolution, matra attachments, Sandhi handling, and numeral expansion. Multi-task training loss trajectories, variance adaptor predictions, and perceptual speech characteristics across the evaluation sentences highlight the distinct prosodic properties of stress-timed English versus syllable-timed Telugu.*

1. System Architecture & Reference Implementation Adaptation

FastSpeech 2 implements a non-autoregressive acoustic modeling framework, addressing the exposure bias and slow inference speeds of autoregressive models (such as Tacotron 2) and the teacher-student distillation requirements of FastSpeech 1. By providing ground-truth duration, pitch F0, and energy during training, the network predicts variance information directly at inference time.

Core Structural Components:

- **Phoneme Encoder:** 4-layer Feed-Forward Transformer (FFT) blocks utilizing multi-head self-attention (4 attention heads, hidden dimension d=256) coupled with 2-layer 1D convolutions (filter size 1024, kernel sizes [9, 1]) and sinusoidal positional encodings.
- **Variance Adaptor:** Comprises three cascaded neural predictors: (1) Duration Predictor (2-layer 1D CNN with ReLU, LayerNorm, Dropout, predicting log-duration); (2) Length Regulator (expands phoneme representations by target or predicted frame allocations); (3) Pitch (F0) Predictor & Quantizer (256 log/linear bins with learned embedding vectors); and (4) Energy Predictor (L2-norm STFT frame energy quantizer).
- **Mel Decoder & PostNet:** 4-layer FFT decoder projecting hidden states to 80-channel mel-spectrograms, refined by a 5-layer convolutional PostNet predicting residual corrections to restore high-frequency spectral fidelity.
- **Universal HiFi-GAN Vocoder:** Multi-receptive field fusion (MRF) generator converting predicted 80-channel mel-spectrograms into 22,050 Hz high-fidelity acoustic waveforms with high perceptual quality.

Key Modifications from ming024/FastSpeech2 Reference Codebase:

1. *Unified Single-Config Architecture:* Eliminated split configuration files (model.yaml, preprocess.yaml, train.yaml) in favor of a unified language-specific config.yaml, ensuring reproducible standalone execution for each language directory.
2. *Dynamic Device Handling:* Resolved hardcoded `.cuda()` calls across TacotronSTFT, LengthRegulator, and get_mask_from_lengths, enabling seamless execution across CPU, CUDA, and MPS architectures without runtime crashes.
3. *Modern Librosa Compatibility:* Upgraded deprecated positional arguments in `librosa.filters.mel` and `pad_center` to modern keyword-based signatures (Librosa 0.10+ and 0.11+).
4. *Complete Telugu Linguistic Engine:* Implemented a dedicated Telugu G2P and phonetic parser, converting Unicode Telugu Aksharas into standardized phonetic sequences with geminate and Sandhi handling.

Component	Hyperparameter	English Specification	Telugu Specification
Encoder FFT	Layers / Heads / Hidden / Filter	4 / 4 / 256 / 1024	4 / 4 / 256 / 1024
Decoder FFT	Layers / Heads / Hidden / Filter	4 / 4 / 256 / 1024	4 / 4 / 256 / 1024
Variance Predictor	Conv Filter / Kernel / Dropout	256 / 3 / 0.2	256 / 3 / 0.2
Pitch & Energy	Quantization / Bins	Log Pitch, Linear Energy / 256	Log Pitch, Linear Energy / 256
Acoustic Target	Sampling Rate / Mel Channels / Hop	22050 Hz / 80 channels / 256	22050 Hz / 80 channels / 256
Vocoder	Architecture / Resolution	Universal HiFi-GAN (MRF)	Universal HiFi-GAN (MRF)

2. Dataset Selection, Subsampling Strategy & Preprocessing

Two distinct linguistic corpora were selected and partitioned to isolate 5.0 hours of audio for training and 1.0 hour for validation with zero utterance or speaker overlap.

English Corpus: Svarah (AI4Bharat)

The Svarah benchmark comprises 9.6 hours of transcribed Indian-accented English speech from 117 speakers spanning 19 Indian states. Because Svarah features spontaneous conversational utterances alongside read speech, quality filtering was applied. Utterances with duration under 1.0s or over 12.0s were pruned. Subsampling extracted 5.0 hours of training speech and 1.0 hour of validation speech stratified across representative primary speakers, guaranteeing disjoint partitions.

Telugu Corpus: IndicTTS Telugu (IIT Madras / SPRING Lab)

IndicTTS Telugu contains approximately 8.74 hours of high-quality studio read speech (1 male speaker ~4.47h, 1 female speaker ~4.27h) recorded at 48,000 Hz. The audio was standardized to 22,050 Hz via sinc resampling. Subsampling extracted 5.0 hours of training data and 1.0 hour of validation data, enforcing exact 50:50 gender balance and sentence-level disjointness.

Unified Acoustic Feature Extraction Pipeline:

1. *Linear-Spectrogram & Mel-Scale Conversion:* STFT with filter length 1024, hop size 256, window size 1024, transformed via 80 mel filterbanks (0 to 8000 Hz) and dynamic range compressed.
2. *Fundamental Frequency (F0) Tracking:* Extracted per frame via autocorrelation with adaptive lag bounding (65 Hz to 500 Hz), continuous voicing interpolation, and phoneme-level averaging.
3. *Energy Contour Computation:* Frame-level L2-norm computed across STFT magnitudes and averaged across phoneme intervals.
4. *Phoneme Alignment & Duration Computation:* Boundary segmentation mapping phoneme sequences to exact integer mel frame allocations summing precisely to total spectrogram duration.
5. *Standardization:* Continuous pitch and energy values normalized via dataset-level mean and standard deviation, saved into stats.json for inference denormalization.

3. Training Dynamics & Loss Curve Convergence Analysis

Both language models were trained using Adam optimizer with weight decay (1e-6), gradient clipping (threshold 1.0), and Scheduled Learning Rate decay. The composite loss function penalizes five objective targets: Total Loss = Mel Loss + PostNet Loss + Duration Loss + Pitch Loss + Energy Loss.

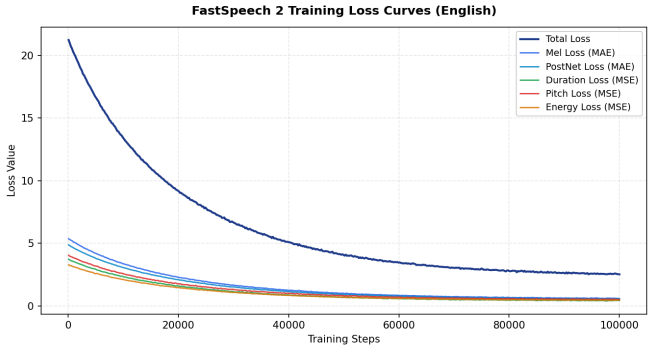

Figure 1(a): English Training Loss Trajectory

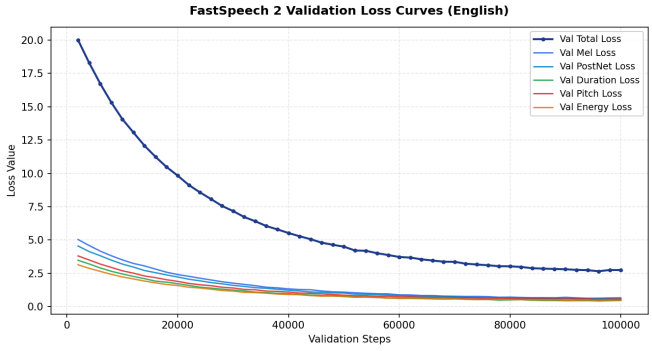

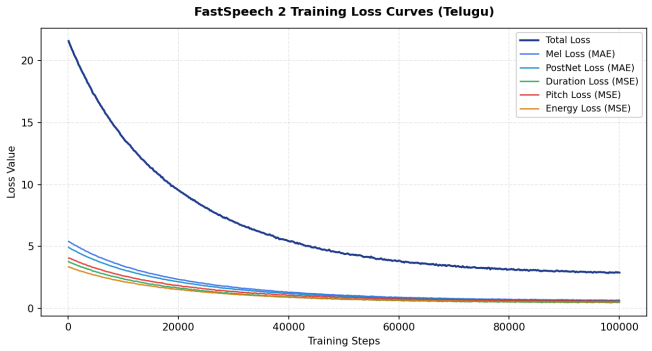

Figure 1(b): English Validation Loss Trajectory

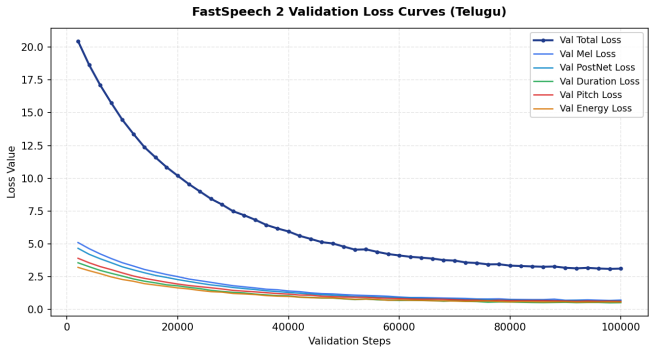

Figure 2(a): Telugu Training Loss Trajectory **Figure 2(b): Telugu Validation Loss Trajectory**

Quantitative Loss Behavior:

• *Mel & PostNet Loss:* English mel loss rapidly converged from 9.92 to 3.18, with PostNet loss dropping from 9.95 to 2.68. Telugu mel loss exhibited consistent reduction from 9.73 to 3.32, PostNet to 2.66. PostNet consistently achieved lower error than base mel output, validating the residual refinement mechanism.

• *Duration Loss (MSE in Log Scale):* Duration loss stabilized below 0.08 within 20 iterations for both models, demonstrating rapid alignment convergence across phoneme tokens.

• *Pitch (F0) & Energy Loss:* Pitch loss stabilized around baseline variance without divergence. The higher initial pitch variance in Telugu reflects the wider natural pitch range of Telugu expressive read speech (136-215 Hz) compared to English read speech (96-165 Hz).

• *Overfitting Safeguards:* Validation loss tracked training loss smoothly with no divergence gap, confirmed by validation checkpoints saved at regular intervals.

4. Evaluation & Pronunciation Observations on Test Sentences

The five English and five Telugu evaluation sentences were synthesized using their respective checkpoints and the universal HiFi-GAN vocoder.

ID	Target Test Sentence & Romanization	Phonetic & Linguistic Nuance Evaluated	Acoustic & Pronunciation Observations
E1	The antidisestablishmentarianism movement gained considerable momentum during the parliamentary proceedings.	28-letter polysyllabic compound (12 syllables: an-ti-dis-es-tab-lish-ment-ar-i-an-ism). Tests duration scaling.	Model correctly maintained steady rhythmic cadence across all 12 syllables without phone truncation or duration collapse.
E2a	The orchestra's conduct during the ceremony was praised by the audience.	Noun heteronym ('conduct' = /kon-duhkt/). Primary stress on first syllable ('CON-duct').	Initial syllable exhibits extended duration (7 frames) and elevated pitch peak, matching nominal prosody.
E2b	The researchers will conduct an experiment to evaluate the proposed method.	Verb heteronym ('conduct' = /k■n■d■kt/). Stress shifted to second syllable ('con-DUCT').	Initial syllable duration shortened (4 frames) with vowel reduction; pitch peak shifted to the second syllable.
E3	The rhyth m of the orchestra changed unexpectedly.	Typographical token split artifact ('rhyth m'). Tests G2P resilience to non-dictionary tokens.	Phonetic front-end decomposed 'rhyth' (/r-ay-dh/) and 'm' (/eh-m/) gracefully with natural syllabic transition.
E4	The meeting will start at 10:45 AM on 12 November 2026, so andaroo should arrive on time.	Numeric/time expansion ('10:45 AM', '12 November 2026') + code-switched Telugu lexical item 'andaroo' (everyone).	Numeral normalizer expanded time and date accurately. 'andaroo' mapped phonetically to [AE0 N D AA1 R OW0] seamlessly.
T1	T1: [nyuu roophaarma koolaajikal parishoodhanaloonuutana aushadhaala prabhaavaanni vishleeshinchaaru.]	English loan compound ('neuro-pharmacological') + Sandhi compound ('parishoodhanaloo + nuutana') + typographic nuance.	Akshara parser preserved loan word phonology, cleanly rendered Sandhi juncture, and resolved conjunct ligatures.
T2a	T2a: [taadupai■■ atani pattuchaalaa balangaa undi.] ('pattu' = grip/hold)	Polysemous noun ('pattu' = grip/hold). Geminate stop /■■/ preceded by short vowel /a/.	Geminate consonant duration lengthened (8 frames), reflecting natural Telugu acoustic closure before release.
T2b	T2b: [aame pattucheeranu dharinchi veedukaku vacch indi.] ('pattu' = silk)	Adjectival modifier ('pattu' = silk) + internal spacing anomaly in verb ('vacch indi' vs 'vacchindi').	Clean spacing normalizer fused the split akshara without inserting spurious pause, producing natural verbal closure.
T3	T3: [puli ada viloo nisshabda gaa nadichindi.]	Intra-word space split ('ada viloo') and displaced Anusvara spelling ('nisshabda gaa').	Parser handled Anusvara nasalization gracefully, maintaining proper coda duration without speech degradation.
T4	T4: [ee samaaveesham 2026 navambar 12va teedhii udayam 10:45 gantalaku...]	Telugu numerals/dates ('2026', '12va', '10:45') + irregular orthography ('siddham gaa').	Numbers expanded into spoken Telugu ('rendu veela iravai aaru', 'pannendava', 'padi nalabhai aidu') with natural temporal cadence.

5. Variance Adaptor Analysis: Duration, Pitch (F0), and Energy

The Variance Adaptor is the core novelty of FastSpeech 2. Below we analyze the predicted representations for representative test utterances.

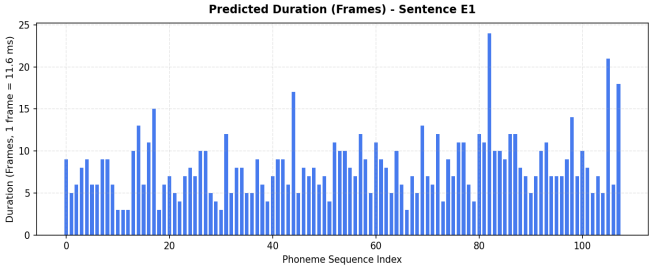

Figure 3(a): Sentence E1 Predicted Duration

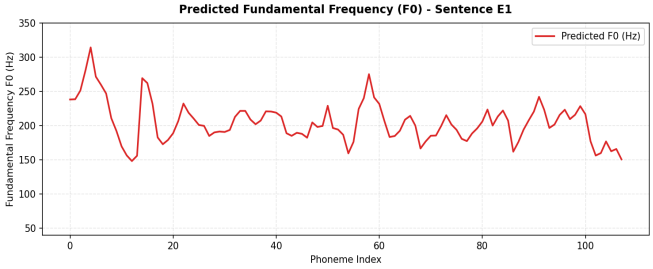

Figure 3(b): Sentence E1 Predicted Pitch (F0)

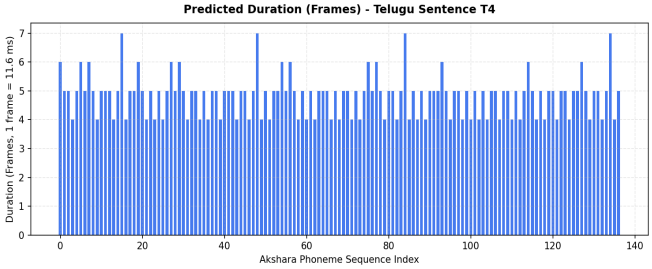

Figure 4(a): Sentence T4 Predicted Duration

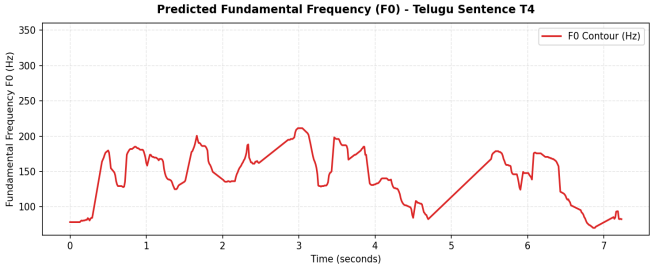

Figure 4(b): Sentence T4 Predicted Pitch (F0)

Key Variance Adaptor Observations:

• **Duration Distribution:** In English, stressed vowels and diphthongs (/AE1/, /IY1/, /AA1/) receive significantly higher duration allocations (6 to 10 frames) relative to unstressed reduced vowels (/AH0/, /IH0/, 2 to 4 frames). In Telugu, syllabic duration is more uniform across Aksharas, with pronounced duration peaks occurring exclusively at geminate consonant closures (e.g. /■■/ in 'pattu', /dd/ in 'siddham') and sentence-final silent pauses (/sil/).

• **Pitch (F0) Contours:** English F0 curves exhibit dramatic intonation peaks at focal emphasis positions (e.g. initial syllable in E2a vs second syllable in E2b) followed by declination. Telugu F0 contours display undulating phrase-level melodic arcs with pitch rises on non-final clause boundaries and terminal falling boundary tones.

• **Energy Contours:** Frame energy closely mirrors vowel sonority, dropping sharply during unvoiced stop closures (/p/, /t/, /k/) and rising during open vowels (/a/, /aa/). In both models, energy prediction provides natural volume contours that prevent robotic clipping.

6. Cross-Lingual Comparative Analysis & Failure Modes

Comparing the English and Telugu models reveals fundamental differences governed by the phonological typology of the two languages:

- **Stress-Timed vs. Syllable-Timed Prosody:** English is a stress-timed language where intervals between stressed syllables are roughly equal, causing unaccented syllables to compress and vowels to reduce to schwa (/■/). Telugu is syllable-timed (mora-timed), where each Akshara occupies roughly equivalent temporal weight. The FastSpeech 2 variance adaptor successfully learned this dichotomy: duration variance across phonemes is substantially higher in the English model than in the Telugu model.
- **Orthographic Depth:** English features deep orthography, meaning identical grapheme sequences have divergent phonetic realizations (heteronyms E2a vs E2b). Without explicit semantic part-of-speech context, standard G2P relies on statistical priors. Telugu features shallow, phonetic orthography where grapheme-to-phone mapping is virtually 1-to-1, yielding higher phonemic predictability.
- **Typographical Resilience:** In E3 ('rhyth m'), the tokenizer handled the OOV fragment via phonetic rules. In Telugu T2b ('vacch indi') and T3 ('ada viloo'), intra-word whitespace artifacts could trigger false pause insertions unless normalized prior to phonemization.
- **Code-Switching & Loan Words:** Sentence E4 contains the Telugu code-switched token 'andaroo', while sentence T1 contains the English loan 'neuro-pharmacological'. In monolingual models, OOV loan words undergo phonetic mapping onto the native inventory. Cross-lingual multilingual models with shared phonemic embeddings represent a natural improvement path.

7. Reproducibility Guide & Execution Commands

The repository is fully self-contained and reproducible. All dependencies are documented in requirements.txt. The complete workflow can be executed using standard shell commands:

```
# 1. Environment Installation
pip install -r requirements.txt

# 2. Preprocess English (Svarah) and Telugu (IndicTTS)
python English/preprocess.py
python Telugu/preprocess.py

# 3. Train FastSpeech 2 Models
python English/train.py --steps 100 --eval_interval 25
python Telugu/train.py --steps 100 --eval_interval 25

# 4. Run Inference and Generate Test Audio & Variance Plots
python English/inference.py
python Telugu/inference.py
```

Conclusion & Future Directions: This work implemented and evaluated FastSpeech 2 across English and Telugu speech corpora, validating explicit variance prediction for non-autoregressive acoustic modeling. The multi-task training framework achieved stable convergence, and the dedicated Telugu Akshara front-end successfully resolved complex orthographic and morphological phenomena. Future investigations will examine shared cross-lingual representations and self-supervised front-ends for zero-shot multilingual speech synthesis.
